## Data Ellipses: 2D contours of a bivariate density

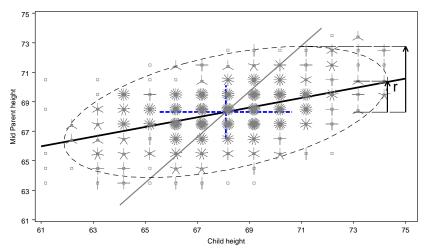

#### Data Ellipses: Galton's data

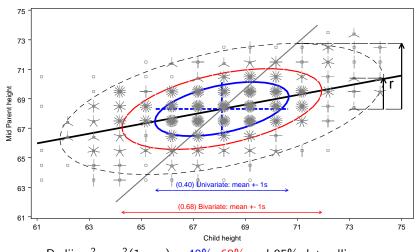

Galton's data on Parent & Child height

## Data Ellipses: Galton's data

Data ellipse: Shows means, std. devs, regression lines, correlation

## Data Ellipses: Galton's data

Radii:  $c^2 = \chi_p^2 (1 - \alpha)$ — 40%, 68% and 95% data ellipses

## The Data Ellipse: Details

#### Visual summary for bivariate relations

- Shows: means, standard deviations, correlation, regression line(s)
- **Defined**: set of points whose squared Mahalanobis distance  $< c^2$ .

$$D^{2}(\mathbf{y}) \equiv (\mathbf{y} - \bar{\mathbf{y}})^{\mathsf{T}} \, \mathbf{S}^{-1} \, (\mathbf{y} - \bar{\mathbf{y}}) \leq c^{2}$$

S = sample variance-covariance matrix

- Radius: when y is  $\approx$  bivariate normal,  $D^2(y)$  has a large-sample  $\chi^2$ distribution with 2 degrees of freedom.
  - $c^2=\chi_2^2(0.40)\approx 1$ : 1 std. dev univariate ellipse– 1D shadows:  $\bar{y}\pm 1s$   $c^2=\chi_2^2(0.68)=2.28$ : 1 std. dev bivariate ellipse

  - $c^2 = \chi_2^2(0.95) \approx 6$ : 95% data ellipse, 1D shadows: Scheffé intervals
- **Construction**: Transform the unit circle,  $\mathcal{U} = (\sin \theta, \cos \theta)$ ,

$$\mathcal{E}_c = \bar{\mathbf{y}} + c\mathbf{S}^{1/2}\mathcal{U}$$

 $\mathbf{S}^{1/2} = \text{any "square root" of } \mathbf{S} \text{ (e.g., Cholesky)}$ 

- Robustify: Use robust estimate of S, e.g., MVE (mimimum volume ellipsoid)
- p variables: Extends naturally to p-dimensional ellipsoids

#### The univariate linear model

- Model:  $\mathbf{y}_{n\times 1} = \mathbf{X}_{n\times q} \, \boldsymbol{\beta}_{q\times 1} + \boldsymbol{\epsilon}_{n\times 1}$ , with  $\boldsymbol{\epsilon} \sim \mathcal{N}(\mathbf{0}, \sigma^2 \mathbf{I}_n)$
- LS estimates:  $\hat{\beta} = (\mathbf{X}^{\mathsf{T}}\mathbf{X})^{-1}\mathbf{X}^{\mathsf{T}}\mathbf{y}$
- General Linear Test:  $H_0$ :  $C_{h\times q}\beta_{q\times 1}=0$ , where C= matrix of constants; rows specify h linear combinations or contrasts of parameters.
- e.g., Test of  $H_0: \beta_1 = \beta_2 = 0$  in model  $y_i = \beta_0 + \beta_1 x_{1i} + \beta_2 x_{2i} + \epsilon_i$

$$\mathbf{C}oldsymbol{eta} = \left[ egin{array}{ccc} 0 & 1 & 0 \ 0 & 0 & 1 \end{array} 
ight] \left( egin{array}{c} eta_0 \ eta_1 \ eta_2 \end{array} 
ight) = \left( egin{array}{c} 0 \ 0 \end{array} 
ight)$$

• All  $\rightarrow$  F-test: How big is  $SS_H$  relative to  $SS_F$ ?

$$F = \frac{SS_H/\mathrm{df}_h}{SS_E/\mathrm{df}_e} = \frac{MS_H}{MS_E} \longrightarrow (MS_H - F MS_E) = 0$$

#### The multivariate linear model

- Model:  $\mathbf{Y}_{n \times p} = \mathbf{X}_{n \times q} \mathbf{B}_{q \times p} + \mathbf{U}$ , for p responses,  $\mathbf{Y} = (\mathbf{y}_1, \mathbf{y}_2, \dots, \mathbf{y}_p)$
- General Linear Test:  $H_0: C_{h\times q} B_{q\times p} = \mathbf{0}_{h\times p}$
- Analogs of sums of squares,  $SS_H$  and  $SS_E$  are  $(p \times p)$  matrices, H and E,

$$\begin{split} \boldsymbol{H} &= (\boldsymbol{C}\widehat{\boldsymbol{B}})^T [\boldsymbol{C}(\boldsymbol{X}^T\boldsymbol{X})^- \boldsymbol{C}^T]^{-1} (\boldsymbol{C}\widehat{\boldsymbol{B}}) \ , \\ \boldsymbol{E} &= \boldsymbol{U}^T \boldsymbol{U} = \boldsymbol{Y}^T [\boldsymbol{I} - \boldsymbol{H}] \boldsymbol{Y} \ . \end{split}$$

Analog of univariate F is

$$\det(\mathbf{H} - \lambda \mathbf{E}) = 0 ,$$

- How big is **H** relative to **E**?
  - Latent roots  $\lambda_1, \lambda_2, \dots \lambda_s$  measure the "size" of **H** relative to **E** in  $s = \min(p, df_h)$  orthogonal directions.
  - Test statistics (Wilks' Λ, Pillai trace criterion, Hotelling-Lawley trace criterion, Roy's maximum root) all combine info across these dimensions

Tubb, Parker & Nicholson analyzed the chemical composition of 26 samples of Romano-British pottery found at four kiln sites in Britain.

- Sites: Ashley Rails, Caldicot, Isle of Thorns, Llanedryn
- Variables: aluminum (Al), iron (Fe), magnesium (Mg), calcium (Ca) and sodium (Na)
- ullet One-way MANOVA design, 4 groups, 5 responses

Friendly, Sigal ()

#### Questions:

- Can the content of Al, Fe, Mg, Ca and Na differentiate the sites?
- How to understand the contributions of chemical elements to discrimination?

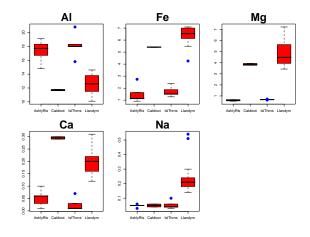

#### Numerical answers:

#### What have we learned?

- Can: YES! We can discriminate sites.
- But: **How to understand** the pattern(s) of group differences: ???

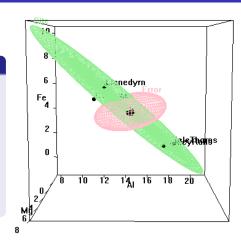

#### Univariate plots are limited

• Do not show the *relations* of variables to each other

#### Visual answer: HE plot

- Shows variation of means (H) relative to residual (E) variation
- Size and orientation of H wrt E: how much and how variables contribute to discrimination
- Evidence scaling: H is scaled so that it projects outside **E** iff null hypothesis is rejected.

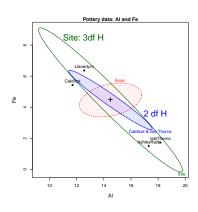

R> heplot3d(pottery.mod)

#### HE plot details: Contrasts and linear hypotheses

- An overall effect  $\mapsto$  an **H** ellipsoid of  $s = \min(p, df_h)$  dimensions
- Linear hypotheses, of the form  $H_0: \mathbf{C}_{h \times q} \, \mathbf{B}_{q \times p} = \mathbf{0}_{h \times p} \mapsto \text{sub-ellipsoid of dimension } h$
- 1D tests and contrasts → degenerate 1D ellipses (lines)

#### HE plot details: Contrasts and linear hypotheses

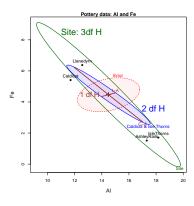

- An overall effect  $\mapsto$  an **H** ellipsoid of  $s = \min(p, df_h)$  dimensions
- Linear hypotheses, of the form  $H_0: \mathbf{C}_{h \times q} \, \mathbf{B}_{q \times p} = \mathbf{0}_{h \times p} \mapsto \text{sub-ellipsoid of dimension } h$
- 1D tests and contrasts → degenerate 1D ellipses (lines)

Friendly, Sigal ()

### HE plot details: Contrasts and linear hypotheses

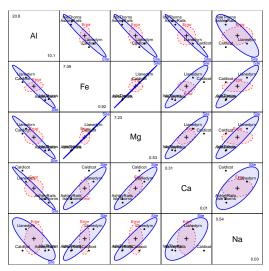

- An overall effect → an H ellipsoid of  $s = \min(p, df_h)$  dimensions
- Linear hypotheses, of the form  $H_0: \mathbf{C}_{h\times q} \, \mathbf{B}_{q\times p} = \mathbf{0}_{h\times p} \mapsto \text{sub-ellipsoid of}$ dimension h
- 1D tests and contrasts → degenerate 1D ellipses (lines)

Friendly, Sigal ()

## HE plot matrices: All bivariate views

AL stands out  $r(\overline{Fe}, \overline{Mg}) \approx 1$ 

R> pairs(pottery.mod)

## HE plots for Multivariate Multiple Regression

- **Model**: Y = XB + U, where cols of X are quantitative.
- **Overall test**:  $H_0$ : B = 0 (all coefficients for all responses are zero)

$$ullet$$
  $ightarrow$   $ightar$ 

• Individual predictors:  $H_0: \beta_i = \mathbf{0}$ 

$$ullet$$
  $ullet$   $\mathbf{C} = (0,0,\ldots,1,0,\ldots,0) 
ightarrow \mathbf{H}_i = \hat{eta}_i^\mathsf{T} (\mathbf{X}^\mathsf{T} \mathbf{X})^{-1} \hat{eta}_i$ 

- HE plot
  - Overall H ellipse: how predictors relate collectively to responses
  - Individual **H** ellipses (rank(**H** )=1  $\rightarrow$  vectors):
    - orientation  $\rightarrow$  relation of  $x_i$  to  $y_1, y_2$

    - collection of individual H vectors → how predictors contribute to overall test.

## HE plots for Multivariate Multiple Regression

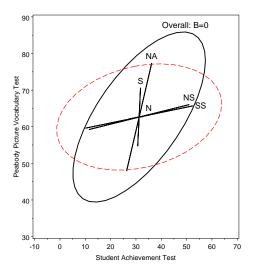

- **Model**: Y = XB + U, where cols of X are quantitative.
- **Overall test**:  $H_0$ : B = 0 (all coefficients for all responses are zero)

$$ullet$$
  $ightarrow$   $ightar$ 

- Individual predictors:  $H_0: \beta_i = \mathbf{0}$ 
  - $\bullet \to \mathbf{C} = (0, 0, \dots, 1, 0, \dots, 0) \to \mathbf{H}_i = \hat{\beta}_i^\mathsf{T} (\mathbf{X}^\mathsf{T} \mathbf{X})^{-1} \hat{\beta}_i$
- HE plot
  - Overall H ellipse: how predictors relate collectively to responses
  - Individual H ellipses (rank(H )=1 → vectors):
    - orientation  $\rightarrow$  relation of  $x_i$  to  $y_1, y_2$
    - ullet length o strength of relation
    - collection of individual H vectors → how predictors contribute to overall test.

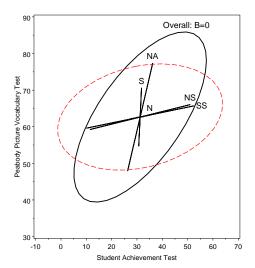

#### HE plots for MMRA: Example

- Rohwer data on n = 37 low SES children, for 5 PA tasks (N, S, NS, NA, SS) predicting intelligence/achievement (PPVT, SAT, Raven)
- Only NA is individually significant (in this view)
- ... but overall test highly significant
- NA & S contribute to predicting PPVT
- NS & SS contribute to predicting SAT

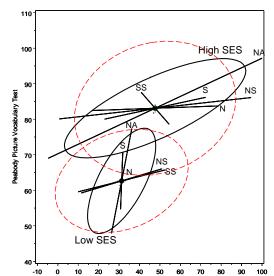

#### HE plots for MMRA: Example

- Rohwer data on n = 37 low SES children, for 5 PA tasks (N, S, NS, NA, SS) predicting intelligence/achievement (PPVT, SAT, Raven)
- Only NA is individually significant (in this view)
- ... but overall test highly significant
- NA & S contribute to predicting PPVT
- NS & SS contribute to predicting SAT

#### HE plots for MMRA: MANCOVA

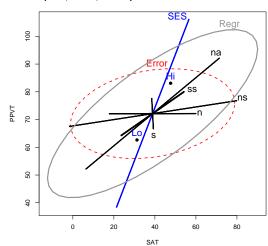

- Rohwer data on  $n_1 = 37$  low SES, and  $n_2 = 32$  high SES children
- Are regressions parallel?
- Are they coincident?
- Fit separate regressions for each group

#### HE plots for MMRA: MANCOVA

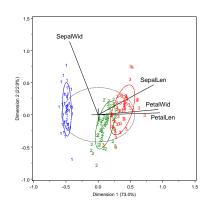

- Rohwer data on  $n_1 = 37$  low SES, and  $n_2 = 32$  high SES children
- Fit MANCOVA model (assuming equal slopes)

(SAT, PPVT, Raven) ~ SES + n + s + ns + na + ss

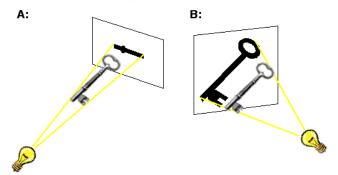

#### Outline

- Background
  - Visual overview
    - Data ellipses
  - The Multivariate Linear Model
  - Motivating example
- 2 Hypothesis-Error (HE) plots
  - Visualizing H and E (co)variation
  - MANOVA designs
  - MREG designs
- Reduced-rank displays
  - Low-D displays of high-D data
  - Canonical discriminant HE plots
- Recent extensions
  - Robust MLMs
  - Influence diagnostics for MLMs
- Conclusion

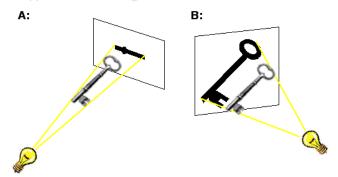

#### Low-D displays of high-D data

- High-D data often shown in 2D (or 3D) views— orthogonal projections in variable space
- Dimension-reduction techniques: project the data into subspace that has the
- ullet ightarrow low-D approximation to high-D data

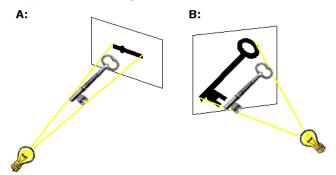

#### Low-D displays of high-D data

- High-D data often shown in 2D (or 3D) views— orthogonal projections in variable space
- Dimension-reduction techniques: project the data into subspace that has the largest shadow— e.g., accounts for largest variance.
- → low-D approximation to high-D data

#### Low-D displays of high-D data

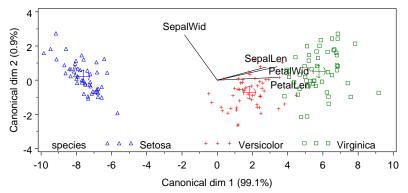

- High-D data often shown in 2D (or 3D) views— orthogonal projections in variable space
- Dimension-reduction techniques: project the data into subspace that has the largest shadow— e.g., accounts for largest variance.
- → low-D approximation to high-D data

A: minimum-variance projection; B: maximum variance projection

## Canonical discriminant HE plots

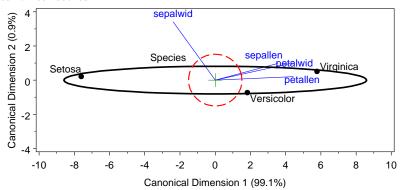

- As with biplot, we can visualize MLM hypothesis variation for all responses by projecting H and E into low-rank space.
- Canonical projection:  $\mathbf{Y}_{n \times p} \mapsto \mathbf{Z}_{n \times s} = \mathbf{Y} \mathbf{E}^{-1/2} \mathbf{V}$ , where  $\mathbf{V} =$  eigenvectors of  $\mathbf{H} \mathbf{E}^{-1}$ .
- This is the view that maximally discriminates among groups, ie max. H wrt
   E!

Friendly, Sigal ()

### Canonical discriminant HE plots

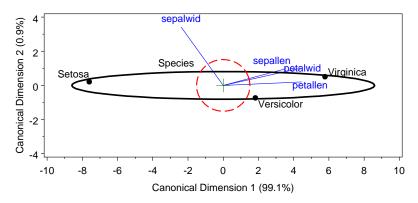

- Canonical HE plot is just the HE plot of canonical scores,  $(z_1, z_2)$  in 2D,
- or,  $z_1, z_2, z_3$ , in 3D.
- As in biplot, we add vectors to show relations of the  $\mathbf{y}_i$  response variables to the canonical variates.
- variable vectors here are structure coefficients = correlations of variables with canonical scores.

Friendly, Sigal ()

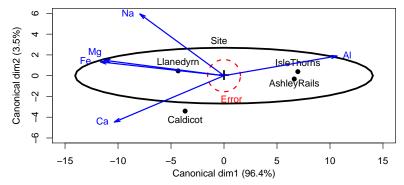

## Canonical discriminant HE plots: Properties

- Canonical variates are uncorrelated: **E** ellipse is spherical
- $\mapsto$  axes must be equated to preserve geometry
- Variable vectors show how variables discriminate among groups
- Lengths of variable vectors  $\sim$  contribution to discrimination

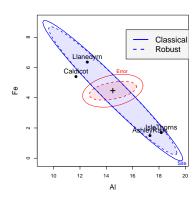

## Canonical discriminant HE plots: Pottery data

- Canonical HE plots provide 2D (3D) visual summary of **H** vs. **E** variation
- Pottery data: p = 5 variables, 4 groups  $\mapsto df_H = 3$
- Variable vectors: Fe, Mg and Al contribute to distingiushing (Caldicot, Llandryn) from (Isle Thorns, Ashley Rails): 96.4% of mean variation
- Na and Ca contribute an additional 3.5%. End of story!

#### Outline

- Background
  - Visual overview
    - Data ellipses
  - The Multivariate Linear Model
  - Motivating example
- Hypothesis-Error (HE) plots
  - Visualizing H and E (co)variation
  - MANOVA designs
  - MREG designs
  - Reduced-rank displays
    - Low-D displays of high-D data
  - Canonical discriminant HE plots
- Recent extensions
  - Robust MI Ms
  - Influence diagnostics for MLMs
- Conclusions

#### Robust MI Ms

- R has a large collection of packages dealing with robust estimation:
  - robust::lmrob(), MASS::rlm(), for univariate LMs
  - robust::glmrob() for univariate generalized LMs
  - High breakdown-bound methods for robust PCA and robust covariance estimation
  - However, none of these handle the fully general MLM
- The heplots package now provides robmlm() for robust MLMs:
  - Uses a simple M-estimtor via iteratively re-weighted LS.
  - Weights: calculated from Mahalanobis squared distances, using a simple robust covariance estimator, MASS::cov.trob() and a weight function,  $\psi(D^2)$ .

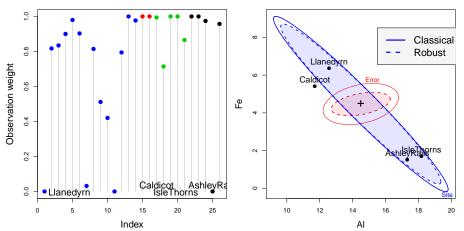

$$D^{2} = (\mathbf{Y} - \widehat{\mathbf{Y}})^{\mathsf{T}} \mathbf{S}_{\text{trob}}^{-1} (\mathbf{Y} - \widehat{\mathbf{Y}}) \sim \chi_{\rho}^{2}$$
 (1)

- This fully extends the "mlm" class
- Compatible with other mlm extensions: car:::Anova and heplots::heplot.
- Downside: Does not incorporate modern consistency factors or other niceties.

Friendly, Sigal ()

## Robust MLMs: Example

#### For the Pottery data:

The **E** ellipse is considerably reduced, enhancing apparent significance

# Influence diagnostics for MLMs

- Influence measures and diagnostic plots are well-developed for univariate LMs
  - Influence measures: Cook's D, DFFITS, dfbetas, etc.
  - Diagnostic plots: Index plots, car:::influencePlot() for LMs
  - However, these are have been unavailable for MLMs
- The mvinfluence package now provides:
  - Calculation for multivariate analogs of univariate influence measures (following Barrett & Ling, 1992), e.g., Hat values & Cook's D:

$$H_I = \mathbf{X}_I (\mathbf{X}^\mathsf{T} \mathbf{X})^{-1} \mathbf{X}_I^\mathsf{T} \tag{2}$$

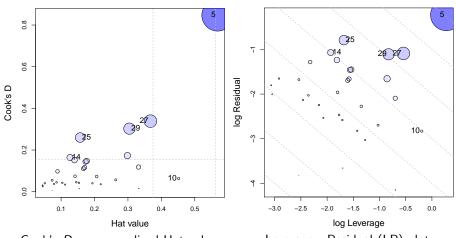

$$D_{l} = [vec(\mathbf{B} - \mathbf{B}_{(l)})]^{\mathsf{T}} [\mathbf{S}^{-1} \otimes (\mathbf{X}^{\mathsf{T}} \mathbf{X})] [vec(\mathbf{B} - \mathbf{B}_{(l)})]$$
(3)

- Provides deletion diagnostics for subsets (1) of size  $m \ge 1$ .
- e.g., m = 2 can reveal cases of masking or joint influence.
- Extension of influencePlot() to the multivariate case.
- A new plot format: leverage-residual (LR) plots.

## Influence diagnostics for MLMs: Example

#### For the Rohwer data:

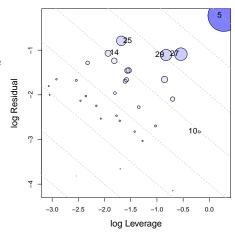

Cook's D vs. generalized Hat value

Leverage - Residual (LR) plot

#### Influence diagnostics for MLMs: LR plots

- Main idea: Influence ∼ Leverage (L) × Residual (R)
- $\bullet \mapsto \log(Infl) = \log(L) + \log(R)$
- on lines with slope = -1.
- Bubble size ∼ influence (Cook's D)
- This simplifies interpretation of influence measures

- Data ellipse: visual summary of bivariate relations
  - Useful for multiple-group, MANOVA data
  - Embed in scatterplot matrix: pairwise, bivariate relations
  - Easily extend to show partial relations, robust estimators, etc.
- **HE plots**: visual summary of multivariate tests for MANOVA and MMRA
  - Group means (MANOVA) or 1-df H vectors (MMRA) aid interpretation
  - Embed in HE plot matrix: all pairwise, bivariate relations
  - Extend to show partial relations: HE plot of "adjusted responses"
- Dimension-reduction techniques: low-rank (2D) visual summaries
  - Biplot: Observations, group means, biplot data ellipses, variable vectors
  - Canonical HE plots: Similar, but for dimensions of maximal discrimination
- Beautiful and useful geometries:
  - Ellipses everywhere; eigenvector-ellipse geometries
  - Visual representation of significance in MLM
  - Opportunities for other extensions

- Data ellipse: visual summary of bivariate relations
  - Useful for multiple-group, MANOVA data
  - Embed in scatterplot matrix: pairwise, bivariate relations
  - Easily extend to show partial relations, robust estimators, etc.
- HE plots: visual summary of multivariate tests for MANOVA and MMRA
  - Group means (MANOVA) or 1-df H vectors (MMRA) aid interpretation
  - Embed in HE plot matrix: all pairwise, bivariate relations
  - Extend to show partial relations: HE plot of "adjusted responses"
- Dimension-reduction techniques: low-rank (2D) visual summaries
  - Biplot: Observations, group means, biplot data ellipses, variable vectors
  - Canonical HE plots: Similar, but for dimensions of maximal discrimination
- Beautiful and useful geometries:
  - Ellipses everywhere; eigenvector-ellipse geometries
  - Visual representation of significance in MLM
  - Opportunities for other extensions
